008

009 Here we present some of the sections left for discussion in the main paper.

010 This supplementary report includes a discussion on Flow Generator, Distortion

011 Density Map, Experimental Setting, and Dataset Samples to illustrate additional

012 motion and scene diversity.

013

014 **1 Flow Generator**

015

016 FLOW360 is created using Blender¹, free and open source 3D creation suite.

017 Blender provides an interface to write add-ons for automating workflows. We

018 create Flow-generator, an add-on written for Blender-v2.92 to collect optical flow

019 and several other data like depth information and normal maps. Flow-generator

020 can be installed using following steps:

021

022 1. Download Flow-generator²

023 2. In Blender-v2.92, follow:

024 – Edit → Preferences → Add-ons → Install

025 – Select flow_generator.py from Flow-generator project folder

026 – Install Add-on

027 – Search FlowGenerator

028 – Check mark for installation

029 3. Setup compositor pipeline in Blender-v2.92

030 – Go to Compositing

031 – Select “SetFlow Generator” from Custom Node Group

032 – If Custom Node Group is disabled press “n” to make it visible

033 – Select desired configuration and click “SetEnv”

034 4. Camera Setup

035 – Go to Layout

036 – Open tab on right side of the Layout view by pressing “n” if not visible

037 – Go to “CameraSetup” on the right tab

038 – Select desired configuration and click “Set Camera System”

039 Note that, we use cloud rendering to speed up the rendering process which

040 requires crowd-render³ add-on. Flow-generator provides two basic functionality:

041 (i) camera setup and (ii) compositor pipeline.

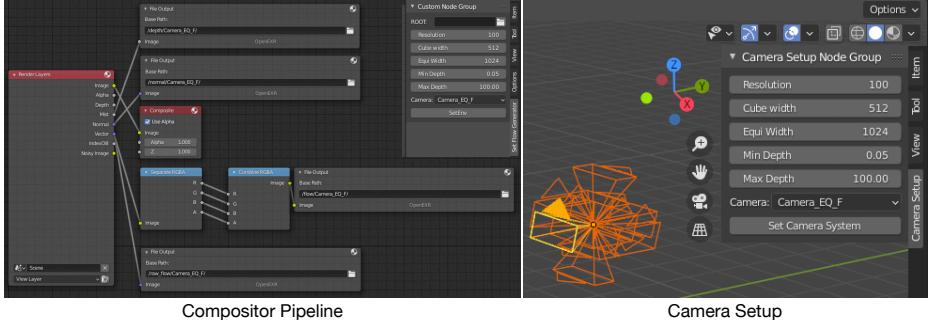

Fig. 1. FlowGenerator. Flow-generator serves two major purposes: (Left) Setting up a compositor pipeline which involves setting up filepaths, pipelining desired output and setting initial configurations like render-engine and render passes. (Right) Setting up camera configurations and additional information like resolution, dimensions and depth of the scene.

1.1 Compositor Pipeline

Compositor in Blender provides a pipeline to process render output. Flow-generator creates a basic pipeline (shown in Fig. 1) to collect information like optical flow, images, depth maps and so on. It also provides an easy way to cache the desired outputs in structured format. Similarly, it also setups basic configurations like selecting render-engine and render passes.

1.2 Camera Setup

Camera Setup (shown in Fig. 1) can be accessed via 3D-Layout tab in Blender-v2.92 as suggested above. Camera Setup creates an omnidirectional camera with full 360° field of view. The camera setup consists of twelve different cameras (six perspective and six 360°) out of which any omnidirectional camera (default Camera_EQ_F) can be selected as main camera for rendering omnidirectional videos. It also provides an interface to adjust configurations like resolution, dimension and depth of the scene.

2 Distortion Density Map

We compute distortion mask ($U_d, D_d, F_d, B_d, R_d, L_d$) in a cube-map with six faces: Up(U), Down(D), Front(F), Back(B), Right(R) and Left(L) respectively. This distortion density cube-map projection is then projected to equirectangular projection using spherical co-ordinate transformation (shown in Eq. 1).

$$(x_s, y_s, z_s) = (\sin \theta \cos \phi, \sin \theta \sin \phi, \cos \theta). \quad (1)$$

To compute density mask (C_d , where $C \in (U, D, F, B, R, L)$) in each face, we define a meshgrid for co-ordinates x and y ranging from $([-1, 1])$ with dimension

of (256, 256). The co-ordinates (x, y) are used to compute a radius map (r) of size (256, 256) as shown in Eq. 2.

$$r = \sqrt{x^2 + y^2} \quad (2)$$

In our paper we have shown that the radial distortion is higher towards central in the polar region which corresponds to (U,D) faces of cube-map projections. Similarly, in equatorial region i.e., rest of the faces (F,R,B,L) shows higher distortion rate away from the center. We compute two distinct distortion map (C_d), one for polar regions (U,D) and another for equatorial regions (F,B,R,L) as shown in Eq. 3

$$C_d = \begin{cases} 1 - r/\max(r) & \text{if, } C \in \{\text{U,D}\} \\ r/\max(r) & \text{otherwise} \end{cases}, \quad (3)$$

Please refer to code⁴ for additional details.

3 Experimental Setting

We conduct our experiment in Pytorch (1.9.0+cuda10.2) using latest version of Python (3.8.10). Additional environment detail is provided in project⁵.

Following are the list of configurations we used for our project:

- Train/Val Batch Size: Ours(16/12 - 8Gpus), Finetune(8/12 - 4 Gpus)
- Number of iterations on RAFT: 12
- Loss: CosineSimilarity, Optical Flow L1-loss
- Optimizer: AdamW
- Scheduler: OneCycleLR
- EarlyStopping: Patience (5) and Min-delta (1e-4)
- Others: Gradient Clipping, GradScaler
- Dataset: FLOW360⁶

We suggest our readers to refer sample videos^{7,8} for demo purpose.

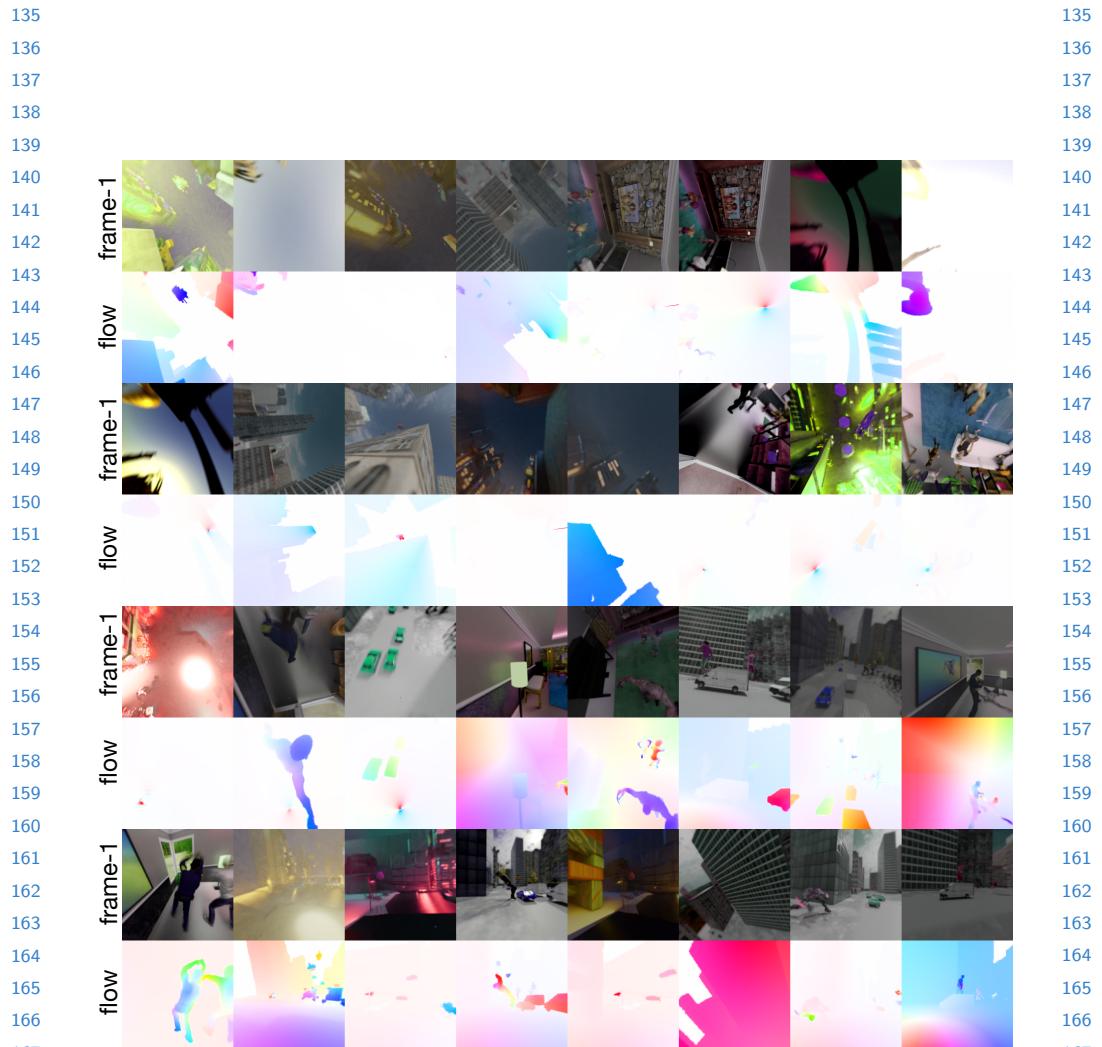

Fig. 2. More Motion and Scene Diversity - Train Set. Illustrating motion and scene diversity via randomly sampled tangential plane from FLOW360 dataset. Flow360 contains range of scene complexity governing varied properties like texture, illumination, human, building, cars and other 3D assets. Similarly, the various level of motion complexity can be seen for similar scenes ranging from smaller to larger displacement. As explained in the main paper the dataset also contains other complexities like motion blur, camera focus/defocus, camera distortion and environmental effects.
